CONVERGENCE ANALYSIS OF ALTERNATING DIRECTION METHOD OF MULTIPLIERS FOR A FAMILY OF NONCONVEX PROBLEMS*

MINGYI HONG[†], ZHI-QUAN LUO[‡], AND MEISAM RAZAVIYAYN[§]

Abstract. The alternating direction method of multipliers (ADMM) is widely used to solve large-scale linearly constrained optimization problems, convex or nonconvex, in many engineering fields. However there is a general lack of theoretical understanding of the algorithm when the objective function is nonconvex. In this paper we analyze the convergence of the ADMM for solving certain nonconvex *consensus* and *sharing* problems. We show that the classical ADMM converges to the set of stationary solutions, provided that the penalty parameter in the augmented Lagrangian is chosen to be sufficiently large. For the sharing problems, we show that the ADMM is convergent regardless of the number of variable blocks. Our analysis does not impose any assumptions on the iterates generated by the algorithm and is broadly applicable to many ADMM variants involving proximal update rules and various flexible block selection rules.

Key words. nonconvex optimization, ADMM, consensus, sharing

1. Introduction. Consider the following linearly constrained (possibly nonsmooth or/and nonconvex) problem with K blocks of variables $\{x_k\}_{k=1}^K$:

$$\min \quad f(x) := \sum_{k=1}^K g_k(x_k) + \ell(x_1, \ldots, x_K)$$

(1.1)

$$\text{s.t.} \quad \sum_{k=1}^K A_k x_k = q, \ x_k \in X_k \quad \forall \ k = 1, \ldots, K,$$

where $A_k \in \mathbb{R}^{M \times N_k}$ and $q \in \mathbb{R}^M$; $X_k \subset \mathbb{R}^{N_k}$ is a closed convex set; $\ell(\cdot)$ is a smooth (possibly nonconvex) function; and each $g_k(\cdot)$ can be either a smooth function or a convex nonsmooth function. Let us define $A := [A_1, \ldots, A_k]$. The augmented Lagrangian for problem (1.1) is given by

$$(1.2) \qquad L(x; y) = \sum_{k=1}^K g_k(x_k) + \ell(x_1, \ldots, x_K) + \langle y, q - Ax \rangle + \frac{\rho}{2} \|q - Ax\|^2,$$

where $\rho > 0$ is a constant representing the primal penalty parameter.

To solve problem (1.1), let us consider a popular algorithm called the alternating direction method of multipliers (ADMM), whose steps are given in Algorithm 0.

Algorithm 0. ADMM for problem (1.1).

At each iteration $t + 1$, update the primal variables:

(1.3)　　$x_k^{t+1} = \arg \min_{x_k \in X_k} L(x_1^{t+1}, \ldots, x_{k-1}^{t+1}, x_k, x_{k+1}^t, \ldots, x_K^t; y^t), \ \forall \ k = 1, \ldots, K.$

Update the dual variable:

(1.4)　　　　　　　　　　　$y^{t+1} = y^t + \rho(q - Ax^{t+1}).$

The ADMM algorithm was originally introduced in the early 1970s [2, 3] and has since been studied extensively [4, 5, 6, 7]. Recently it has become widely popular in modern big data related problems arising in machine learning, computer vision, signal processing, networking, and so on; see [8, 9, 10, 11, 12, 13, 14, 15] and the references therein. In practice, the algorithm often exhibits faster convergence than traditional primal-dual type algorithms such as the dual ascent algorithm [16, 17, 18] or the method of multipliers [19]. It is also particularly suitable for parallel implementation [8].

There is a vast literature that applies the ADMM to various problems in the form of (1.1). Unfortunately, theoretical understanding of the algorithm is still fairly limited. For example, most of its convergence analysis is done for a certain special form of problem (1.1)—the *two-block convex separable* problems, where $K = 2$, $\ell = 0$ and g_1, g_2 are both convex. In this case, ADMM is known to converge under very mild conditions; see [7] and [8]. Under the same conditions, several recent works [20, 21, 22] have shown that the ADMM converges with the sublinear rate of $\mathcal{O}(\frac{1}{t})$ or $o(\frac{1}{t})$, and it converges with a rate $\mathcal{O}(\frac{1}{t^2})$ when properly accelerated [23, 24]. Deng and Yin [25] has shown that the ADMM converges linearly when the objective function as well as the constraints satisfy certain additional assumptions. For the *multiblock* separable convex problems where $K \geq 3$, it is known that the original ADMM can diverge for certain pathological problems [26]. Therefore, most research effort in this direction has been focused on either analyzing problems with additional conditions or showing convergence for variants of the ADMM; see, for example, [26, 27, 28, 29, 30, 31, 32, 33, 34]. It is worth mentioning that when the objective function is not separable across the variables (e.g., the coupling function $\ell(\cdot)$ appears in the objective), the convergence of the ADMM is still open, even in the case where $K = 2$ and $f(\cdot)$ is convex. Recent works of [29, 35] have shown that when problem (1.1) is convex but not necessarily separable, and when a certain error bound condition is satisfied, then the ADMM iteration converges to the set of primal-dual optimal solutions, provided that the dual stepsize decreases in time. Another recent work in this direction can be found in [36].

Unlike the convex case, for which the behavior of ADMM has been investigated quite extensively, when the objective becomes nonconvex, the convergence issue of ADMM remains largely open. Nevertheless, it has been observed by many researchers that the ADMM works extremely well for various applications involving nonconvex objectives, such as the nonnegative matrix factorization [37, 38], phase retrieval [39], distributed matrix factorization [40], distributed clustering [41], sparse zero variance discriminant analysis [42], polynomial optimization[43], tensor decomposition [44], matrix separation [45], matrix completion [46], asset allocation [47], sparse feedback control [48], and so on. However, to the best of our knowledge, existing convergence analysis of ADMM for nonconvex problems is very limited—all known global

convergence analysis needs to impose uncheckable conditions on the sequence generated by the algorithm. For example, [43, 45, 46, 47] show global convergence of the ADMM to the set of stationary solutions for their respective nonconvex problems, by making the key assumptions that the limit points do exist and that the successive differences of the iterates (both primal and dual) converge to zero. However, such assumption is nonstandard and overly restrictive. It is not clear whether the same convergence result can be claimed without making assumptions on the iterates. Zhang [49] analyzes a family of splitting algorithms (which includes the ADMM as a special case) for certain nonconvex quadratic optimization problem and shows that they converge to the stationary solution when a certain condition on the dual stepsize is met. We note that there have been many recent works proposing new algorithms to solve nonconvex and nonsmooth problems, for example, [50, 51, 52, 53, 54]. However, these works do not deal with nonconvex problems with linearly coupling constraints, and their analysis does not directly apply to the ADMM-type methods.

The aim of this paper is to provide some theoretical justification on the good performance of the ADMM for nonconvex problems. Specifically, we establish the convergence of ADMM for certain types of nonconvex problems including the consensus and sharing problems without making any assumptions on the iterates. Our analysis shows that, as long as the objective functions g_k's and ℓ satisfy certain regularity conditions, and the penalty parameter ρ is chosen large enough (with computable bounds), then the iterates generated by the ADMM are guaranteed to converge to the set of stationary solutions. It should be noted that our analysis covers many variants of the ADMM, including per-block proximal update and flexible block selection. An interesting consequence of our analysis is that for a particular reformulation of the sharing problem, the *multiblock* ADMM algorithm converges, regardless of the convexity of the objective function. Finally, to facilitate possible applications to other nonconvex problems, we highlight the main proof steps in our analysis framework that can guarantee the global convergence of the ADMM iterates (1.3)–(1.4) to the set of stationary solutions.

2. The nonconvex consensus problem.

2.1. The basic problem. Consider the following nonconvex global consensus problem with regularization:

$$(2.1) \qquad \min \quad f(x) := \sum_{k=1}^{K} g_k(x) + h(x)$$
$$\text{s.t.} \quad x \in X,$$

where g_k's are a set of smooth, possibly nonconvex functions, while $h(x)$ is a convex nonsmooth regularization term. This problem is related to the convex global consensus problem discussed heavily in [8, section 7], but with the important difference that g_k's can be nonconvex.

In many practical applications, g_k's need to be handled by a single agent, such as a thread or a processor. This motivates the following consensus formulation. Let us introduce a set of new variables $\{x_k\}_{k=0}^{K}$ and transform problem (2.1) equivalently to the following linearly constrained problem:

$$(2.2) \qquad \min \quad \sum_{k=1}^{K} g_k(x_k) + h(x_0)$$
$$\text{s.t.} \quad x_k = x_0 \quad \forall\, k = 1, \dots, K, \quad x_0 \in X.$$

We note that after reformulation, the problem dimension is increased by K due to the introduction of auxiliary variables $\{x_1, \ldots, x_K\}$. Consequently, solving the reformulated problem (2.2) distributedly may not be as efficient (in terms of total number of iterations required) as applying the centralized algorithms [50, 51, 52, 53, 54] directly to the original problem (2.1). Nonetheless, a major benefit of solving the reformulated problem (2.2) is the flexibility of allowing each distributed agent to handle a single *local* variable x_k and a *local* function g_k.

The augmented Lagrangian function is given by

$$(2.3) \quad L(\{x_k\}, x_0; y) = \sum_{k=1}^{K} g_k(x_k) + h(x_0) + \sum_{k=1}^{K} \langle y_k, x_k - x_0 \rangle + \sum_{k=1}^{K} \frac{\rho_k}{2} \|x_k - x_0\|^2.$$

Note that this augmented Lagrangian is slightly different from the one expressed in (1.2), as we have used a set of different penalization parameters $\{\rho_k\}$, one for each equality constraint $x_k = x_0$. We note that there can be many other variants of the basic consensus problem, such as the *general form consensus optimization*, the *sharing* problem, and so on. We will discuss some of those variants in later sections.

2.2. The ADMM algorithm for nonconvex consensus. Problem (2.2) can be solved distributedly by applying the classical ADMM. The details are given in Algorithm 1.

Algorithm 1. The classical ADMM for problem (2.2).

At each iteration $t + 1$, compute

$$(2.4) \quad x_0^{t+1} = \arg\min_{x_0 \in X} L(\{x_k^t\}, x_0; y^t).$$

Each node k computes x_k by solving

$$(2.5) \quad x_k^{t+1} = \arg\min_{x_k} g_k(x_k) + \langle y_k^t, x_k - x_0^{t+1} \rangle + \frac{\rho_k}{2} \|x_k - x_0^{t+1}\|^2.$$

Each node k updates the dual variable:

$$(2.6) \quad y_k^{t+1} = y_k^t + \rho_k \left(x_k^{t+1} - x_0^{t+1} \right).$$

In the x_0 update step, if the nonsmooth penalization $h(\cdot)$ does not appear in the objective, then this step can be written as

$$(2.7) \quad x_0^{t+1} = \arg\min_{x_0 \in X} L(\{x_k^t\}, x_0; y^t) = \text{proj}_X \left[\frac{\sum_{k=1}^{K} \rho_k x_k^t + \sum_{k=1}^{K} y_k^t}{\sum_{k=1}^{K} \rho_k} \right].$$

Note that the above algorithm has the exact form as the classical ADMM described in [8], where the variable x_0 is taken as the first block of primal variable and the collection $\{x_k\}_{k=1}^{K}$ as the second block. The two primal blocks are updated in a sequential (i.e., Gauss–Seidel) manner, followed by an inexact dual ascent step.

In what follows, we consider a more general version of ADMM which includes Algorithm 1 as a special case. In particular, we propose a *flexible* ADMM algorithm in which there is a greater flexibility in choosing the order of the update of both the primal and the dual variables. Specifically, we consider the following two types of variable block update order rules: let $k = 0, 2, ..., K$ be the indices for the primal variable blocks $x_0, x_1, x_2, ..., x_K$, and let $\mathcal{C}^t \subseteq \{0, 1, \ldots, K\}$ denote the set of variables updated in iteration t. Then the following hold:

1. *Randomized update rule*: At each iteration $t + 1$, a variable block k is chosen randomly with probability p_k^{t+1},

(2.8) $$\Pr\left(k \in \mathcal{C}^{t+1} \mid x_0^t, y^t, \{x_k^t\}\right) = p_k^{t+1} \geq p_{\min} > 0.$$

2. *Essentially cyclic update rule*: There exists a given period $T \geq 1$ during which each index is updated at least once. More specifically, at iteration t, update all the variables in an index set $\mathcal{C}^t$ whereby

(2.9) $$\bigcup_{i=1}^{T} \mathcal{C}^{t+i} = \{0, 1, \ldots, K\} \quad \forall\, t.$$

We call this update rule a *period-T* essentially cyclic update rule.

Algorithm 2. The flexible ADMM for problem (2.2).

Let $\mathcal{C}^1 = \{0, \ldots, K\}$, $t = 0, 1, \ldots$.
At each iteration $t + 1$, do:

If $t + 1 \geq 2$, pick an index set $\mathcal{C}^{t+1} \subseteq \{0, \ldots, K\}$.

If $0 \in \mathcal{C}^{t+1}$, compute

(2.10) $$x_0^{t+1} = \operatorname*{argmin}_{x \in X} L(\{x_k^t\}, x_0; y^t).$$

Else $x_0^{t+1} = x_0^t$.
If $k \neq 0$ and $k \in \mathcal{C}^{t+1}$, node k computes x_k by solving

(2.11) $$x_k^{t+1} = \arg\min_{x_k} g_k(x_k) + \langle y_k^t, x_k - x_0^{t+1}\rangle + \frac{\rho_k}{2}\|x_k - x_0^{t+1}\|^2.$$

Update the dual variable:

(2.12) $$y_k^{t+1} = y_k^t + \rho_k\left(x_k^{t+1} - x_0^{t+1}\right).$$

Else $x_k^{t+1} = x_k^t$, $y_k^{t+1} = y_k^t$.

We note that the randomized version of Algorithm 2 is similar to that of the convex consensus algorithms studied in [55] and [56]. It is also related to the *randomized BSUM-M* algorithm studied in [29]. The difference with the latter is that in the randomized BSUM-M, the dual variable is viewed as an additional block that can be randomly picked (independent of the way that the primal blocks are picked), whereas in Algorithm 2, the dual variable y_k is always updated whenever the corresponding primal variable x_k is updated. To the best of our knowledge, the period-T essentially cyclic update rule is a new variant of the ADMM.

Notice that Algorithm 1 is simply the period-1 essentially cyclic rule, which is a special case of Algorithm 2. Therefore we will focus on analyzing Algorithm 2. To this end, we make the following assumption.

Assumption A.
A1. There exists a positive constant $L_k > 0$ such that

$$\|\nabla_k g_k(x_k) - \nabla_k g_k(z_k)\| \leq L_k\|x_k - z_k\| \quad \forall\, x_k, z_k,\ k = 1, \ldots, K.$$

Moreover, h is convex (possible nonsmooth); X is a closed convex set.

A2. For all k, the penalty parameter ρ_k is chosen large enough such that
  1. for all k, the x_k subproblem (2.11) is strongly convex with modulus $\gamma_k(\rho_k)$;
  2. for all k, $\rho_k\gamma_k(\rho_k) > 2L_k^2$ and $\rho_k \geq L_k$.
A3. $f(x)$ is bounded from below over X, that is,

$$\underline{f} := \min_{x \in X} f(x) > -\infty.$$

We have the following remarks regarding the assumptions made above.
- As ρ_k increases, subproblem (2.11) eventually will be strongly convex with respect to x_k. The corresponding strong convexity modulus $\gamma_k(\rho_k)$ is a monotonic increasing function of ρ_k.
- Whenever $g_k(\cdot)$ is nonconvex (therefore $\rho_k > \gamma_k(\rho_k)$), the condition $\rho_k\gamma_k(\rho_k) \geq 2L_k^2$ implies $\rho_k \geq L_k$.
- By construction, $L(\{x_k\}, x_0; y)$ is also strongly convex with respect to x_0, with a modulus $\gamma := \sum_{k=1}^{K} \rho_k$.
- Assumption A makes no assumption on the *iterates* generated by the algorithm. This is in contrast to the existing analysis of the nonconvex ADMM algorithms [37, 43, 46].

Now we begin to analyze Algorithm 2. We first make several definitions. Let $t(k)$ (resp., $t(0)$) denote the latest iteration index that x_k (resp., x_0) is updated before iteration $t + 1$, i.e.,

(2.13)
$$t(k) = \max\{r \mid r \leq t, k \in \mathcal{C}^r\}, \ k = 1, \dots, K,$$
$$t(0) = \max\{r \mid r \leq t, 0 \in \mathcal{C}^r\}.$$

This definition implies that $x_k^t = x_k^{t(k)}$ for all $k = 0, \dots, K$.

Also define new vectors $\hat{x}_0^{t+1}$, $\{\hat{x}_k^{t+1}\}$, $\hat{y}^{t+1}$ and $\{\tilde{x}_k^{t+1}\}$, $\tilde{y}^{t+1}$ by

(2.14a) $$\hat{x}_0^{t+1} = \arg\min_{x_0 \in X} L(\{x_k^t\}, x_0; y^t),$$

(2.14b) $$\hat{x}_k^{t+1} = \arg\min_{x_k} g_k(x_k) + \langle y_k^t, x_k - \hat{x}_0^{t+1}\rangle + \frac{\rho_k}{2}\|x_k - \hat{x}_0^{t+1}\|^2 \ \ \forall \ k,$$

(2.14c) $$\hat{y}_k^{t+1} = y_k^t + \rho_k\left(\hat{x}_k^{t+1} - \hat{x}_0^{t+1}\right),$$

(2.14d) $$\tilde{x}_k^{t+1} = \arg\min_{x_k} g_k(x_k) + \langle y_k^t, x_k - x_0^t\rangle + \frac{\rho_k}{2}\|x_k - x_0^t\|^2 \ \ \forall \ k,$$

(2.14e) $$\tilde{y}_k^{t+1} = y_k^t + \rho_k\left(\tilde{x}_k^{t+1} - x_0^t\right).$$

In other words, $(\hat{x}_0^{t+1}, \{\hat{x}_k^{t+1}\}, \hat{y}^{t+1})$ is a "virtual" iterate assuming that all variables are updated at iteration $t + 1$. $\{\tilde{x}_k^{t+1}\}, \tilde{y}^{t+1}$ is a "virtual" iterate for the case where x_0 is not updated but the rest of the variables are updated.

We first show that the size of the successive difference of the dual variables can be bounded above by that of the primal variables.

LEMMA 2.1. *Suppose Assumption A holds. Then for Algorithm 2 with either a randomized or essentially cyclic update rule, the following are true:*

(2.15a) $$L_k^2\|x_k^{t+1} - x_k^t\|^2 \geq \|y_k^{t+1} - y_k^t\|^2 \ \ \forall \ k = 1, \dots, K,$$

(2.15b) $$L_k^2\|\hat{x}_k^{t+1} - x_k^t\|^2 \geq \|\hat{y}_k^{t+1} - y_k^t\|^2 \ \ \forall \ k = 1, \dots, K,$$

(2.15c) $$L_k^2\|\tilde{x}_k^{t+1} - x_k^t\|^2 \geq \|\tilde{y}_k^{t+1} - y_k^t\|^2 \ \ \forall \ k = 1, \dots, K.$$

Proof. We will show the first inequality. The second and third inequalities follow a similar line of argument.

To prove (2.15a), first note that the case for $k \notin \mathcal{C}^{t+1}$ is trivial, as both sides of (2.15a) evaluate to zero. Suppose $k \in \mathcal{C}^{t+1}$. From the x_k update step (2.11) we have the following optimality condition:

$$
(2.16) \qquad \nabla g_k(x_k^{t+1}) + y_k^t + \rho_k(x_k^{t+1} - x_0^{t+1}) = 0 \quad \forall\, k \in \mathcal{C}^{t+1}/\{0\}.
$$

Combined with the dual variable update step (2.12) we obtain

$$
(2.17) \qquad \nabla g_k(x_k^{t+1}) = -y_k^{t+1} \quad \forall\, k \in \mathcal{C}^{t+1}/\{0\}.
$$

Combining this with Assumption A1, and noting that for any given k, y_k and x_k are always updated in the same iteration, we obtain for all $k \in \mathcal{C}^{t+1}/\{0\}$

$$
\begin{aligned}
\|y_k^{t+1} - y_k^t\| &= \|y_k^{t+1} - y_k^{t(k)}\| \\
&= \|\nabla g_k(x_k^{t+1}) - \nabla g_k(x_k^{t(k)})\| \le L_k \|x_k^{t+1} - x_k^{t(k)}\| = L_k\|x_k^{t+1} - x_k^t\|.
\end{aligned}
$$

The desired result follows. $\square$

Next, we use (2.15a) to bound the difference of the augmented Lagrangian.

LEMMA 2.2.   *For Algorithm 2 with either randomized or period-T essentially cyclic update rule, we have the following:*

$$
\begin{aligned}
&L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^t\}, x_0^t; y^t) \\
(2.18) \qquad &\le \sum_{k \ne 0, k \in \mathcal{C}^{t+1}} \left(\frac{L_k^2}{\rho_k} - \frac{\gamma_k(\rho_k)}{2} \right) \|x_k^{t+1} - x_k^t\|^2 - \frac{\gamma}{2}\|x_0^{t+1} - x_0^t\|^2.
\end{aligned}
$$

Proof. We first split the successive difference of the augmented Lagrangian by

$$
\begin{aligned}
&L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^t\}, x_0^t; y^t) \\
&= \left(L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^{t+1}\}, x_0^{t+1}; y^t) \right) \\
(2.19) \qquad &\quad + \left(L(\{x_k^{t+1}\}, x_0^{t+1}; y^t) - L(\{x_k^t\}, x_0^t; y^t) \right).
\end{aligned}
$$

The first term in (2.19) can be bounded by

$$
\begin{aligned}
&L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^{t+1}\}, x_0^{t+1}; y^t) \\
&= \sum_{k=1}^{K} \langle y_k^{t+1} - y_k^t, x_k^{t+1} - x_0^{t+1}\rangle \\
(2.20) \qquad &\overset{\text{(a)}}{=} \sum_{k \ne 0, k \in \mathcal{C}^{t+1}} \frac{1}{\rho_k} \|y_k^{t+1} - y_k^t\|^2,
\end{aligned}
$$

where in (a) we have used (2.12) and the fact that $y_k^{t+1} - y_k^t = 0$ for all variable block x_k that has not been updated (i.e., $k \ne 0, k \notin \mathcal{C}^{t+1}$). The second term in (2.19) can be bounded by

$$
\begin{aligned}
&L(\{x_k^{t+1}\}, x_0^{t+1}; y^t) - L(\{x_k^t\}, x_0^t; y^t) \\
&= L(\{x_k^{t+1}\}, x_0^{t+1}; y^t) - L(\{x_k^t\}, x_0^{t+1}; y^t) + L(\{x_k^t\}, x_0^{t+1}; y^t) - L(\{x_k^t\}, x_0^t; y^t)
\end{aligned}
$$

$$
\begin{aligned}
&\overset{(a)}{\leq} \sum_{k=1}^{K} \left(\langle \nabla_{x_k} L(\{x_k^{t+1}\}, x_0^{t+1}; y^t), x_k^{t+1} - x_k^t \rangle - \frac{\gamma_k(\rho_k)}{2} \|x_k^{t+1} - x_k^t\|^2 \right) \\
&\qquad + \langle \zeta_{x_0}^{t+1}, x_0^{t+1} - x_0^t \rangle - \frac{\gamma}{2} \|x_0^{t+1} - x_0^t\|^2 \\
&\overset{(b)}{=} \sum_{k\neq 0, k\in \mathcal{C}^{t+1}} \left(\langle \nabla_{x_k} L(\{x_k^{t+1}\}, x_0^{t+1}; y^t), x_k^{t+1} - x_k^t \rangle - \frac{\gamma_k(\rho_k)}{2} \|x_k^{t+1} - x_k^t\|^2 \right) \\
&\qquad + \iota\{0 \in \mathcal{C}^{t+1}\} \left(\langle \zeta_{x_0}^{t+1}, x_0^{t+1} - x_0^t \rangle - \frac{\gamma}{2} \|x_0^{t+1} - x_0^t\|^2 \right) \\
&\overset{(c)}{\leq} - \sum_{k\neq 0, k\in \mathcal{C}^{t+1}} \frac{\gamma_k(\rho_k)}{2} \|x_k^{t+1} - x_k^t\|^2 - \iota\{0 \in \mathcal{C}^{t+1}\} \frac{\gamma}{2} \|x_0^{t+1} - x_0^t\|^2,
\end{aligned}
$$

(2.21)

where in (a) we have used the fact that $L(\{x_k\}, x_0; y)$ is strongly convex w.r.t. each x_k and x_0, with modulus $\gamma_k(\rho_k)$ and γ, respectively, and that

$$
\zeta_{x_0}^{t+1} \in \partial_{x_0} L(\{x_k^t\}, x_0^{t+1}; y^t)
$$

is some subgradient vector; in (b) we have used the fact that when $k \notin \mathcal{C}^{t+1}$ (resp., $0 \notin \mathcal{C}^{t+1}$), $x_k^{t+1} = x_k^t$ (resp., $x_0^{t+1} = x_0^t$), and we have defined $\iota\{0 \in \mathcal{C}^{t+1}\}$ as the indicator function that takes the value 1 if $0 \in \mathcal{C}^{t+1}$ is true and takes value 0 otherwise; and in (c) we have used the optimality of each subproblem (2.11) and (2.10) (where $\zeta_{x_0}^{t+1}$ is specialized to the subgradient vector that satisfies the optimality condition for problem (2.10)).

Combining the above two inequalities (2.20) and (2.21), we obtain

$$
\begin{aligned}
&L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^t\}, x_0^t; y^t) \\
&\leq - \sum_{k\neq 0, k\in \mathcal{C}^{t+1}} \frac{\gamma_k(\rho_k)}{2} \|x_k^{t+1} - x_k^t\|^2 + \sum_{k\neq 0, k\in \mathcal{C}^{t+1}} \frac{1}{\rho_k} \|y_k^{t+1} - y_k^t\|^2 - \iota\{0 \in \mathcal{C}^{t+1}\} \frac{\gamma}{2} \|x_0^{t+1} - x_0^t\|^2 \\
&\leq \sum_{k\neq 0, k\in \mathcal{C}^{t+1}} \left(\frac{L_k^2}{\rho_k} - \frac{\gamma_k(\rho_k)}{2} \right) \|x_k^{t+1} - x_k^t\|^2 - \iota\{0 \in \mathcal{C}^{t+1}\} \frac{\gamma}{2} \|x_0^{t+1} - x_0^t\|^2,
\end{aligned}
$$

where the last inequality is due to (2.15a). The desired result is obtained by noticing the fact that when $0 \notin \mathcal{C}^{t+1}$, we have $x_0^{t+1} - x_0^t = 0$. $\square$

The above result implies that if the condition

(2.22) $$\rho_k \gamma_k(\rho_k) \geq 2L_k^2 \quad \forall\, k = 1, \ldots, K$$

is satisfied, then the value of the augmented Lagrangian function will always decrease. Note that as long as $\gamma_k(\rho_k) \neq 0$, one can always find a ρ_k large enough such that the above condition is satisfied, as the left-hand side of (2.22) is monotonically increasing w.r.t. ρ_k, while the right-hand side (rhs) is a constant.

Next we show that $L(\{x_k^t\}, x_0^t; y^t)$ is in fact convergent.

LEMMA 2.3. *Suppose Assumption* A *is true. Let* $\{\{x_k^t\}, x_0^t, y^t\}$ *be generated by Algorithm* 2 *with either the essentially cyclic rule or the randomized rule. Then the following limit exists and is lower bounded by* $\underline{f}$ *defined in Assumption* A3:

(2.23) $$\lim_{t\to\infty} L(\{x_k^t\}, x_0^t, y^t) \geq \underline{f}.$$

Proof. Notice that the augmented Lagrangian function can be expressed as

$$
\begin{aligned}
&L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) \\
&= h(x_0^{t+1}) + \sum_{k=1}^{K} \left(g_k(x_k^{t+1}) + \langle y_k^{t+1}, x_k^{t+1} - x_0^{t+1} \rangle + \frac{\rho_k}{2} \|x_k^{t+1} - x_0^{t+1}\|^2 \right) \\
&\overset{\text{(a)}}{=} h(x_0^{t+1}) + \sum_{k=1}^{K} \left(g_k(x_k^{t+1}) + \langle \nabla g_k(x_k^{t+1}), x_0^{t+1} - x_k^{t+1} \rangle + \frac{\rho_k}{2} \|x_k^{t+1} - x_0^{t+1}\|^2 \right) \\
&\overset{\text{(b)}}{\geq} h(x_0^{t+1}) + \sum_{k=1}^{K} g_k(x_0^{t+1}) = f(x_0^{t+1}),
\end{aligned}
$$

(2.24)

where (b) comes from the Lipschitz continuity of the gradient of g_k's (Assumption A1) and the fact that $\rho_k \geq L_k$ for all $k = 1, \ldots, K$ (Assumption A2). To see why (a) is true, we first observe that due to (2.17), we have for all $k \neq 0$ and $k \in \mathcal{C}^{t+1}$

$$
\langle y_k^{t+1}, x_k^{t+1} - x_0^{t+1} \rangle = \langle \nabla g_k(x_k^{t+1}), x_0^{t+1} - x_k^{t+1} \rangle.
$$

For all $k \neq 0$ and $k \notin \mathcal{C}^{t+1}$, it follows from $x_k^{t+1} = x_k^t = x_k^{t(k)} = x_k^{t(k)+1}$ and $y_k^{t+1} = y_k^t = y_k^{t(k)} = y_k^{t(k)+1}$ that

$$
\begin{aligned}
\langle y_k^{t+1}, x_k^{t+1} - x_0^{t+1} \rangle &= \langle y_k^{t(k)+1}, x_k^{t(k)+1} - x_0^{t+1} \rangle \\
&= \langle \nabla g_k(x_k^{t(k)+1}), x_0^{t+1} - x_k^{t(k)+1} \rangle = \langle \nabla g_k(x_k^{t+1}), x_0^{t+1} - x_k^{t+1} \rangle.
\end{aligned}
$$

Combining these two cases shows that (a) is true.

Clearly, (2.24) and Assumption A3 together imply that $L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1})$ is lower bounded. This combined with (2.18) says that whenever the penalty parameter ρ_k's are chosen sufficiently large (as per Assumption A2), $L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1})$ is monotonically decreasing and is convergent. This completes the proof. $\square$

We are now ready to prove our first main result, which asserts that the sequence of iterates generated by Algorithm 2 converges to the set of stationary solution of problem (2.2).

THEOREM 2.4. *Assume that Assumption* A *is satisfied. Then we have the following:*

1. *We have* $\lim_{t \to \infty} \|x_k^{t+1} - x_0^{t+1}\| = 0$, $k = 1, \ldots, K$, *deterministically for the essentially cyclic update rule and almost surely (a.s.) for the randomized update rule.*
2. *Let* $(\{x_k^*\}, x_0^*, y^*)$ *denote any limit point of the sequence* $\{\{x_k^{t+1}\}, x_0^{t+1}, y^{t+1}\}$ *generated by Algorithm* 2. *Then the following statement is true (deterministically for the essentially cyclic update rule and a.s. for the randomized update rule):*

$$
0 = \nabla g_k(x_k^*) + y_k^*, \quad k = 1, \ldots, K.
$$

$$x_0^* \in \arg\min_{x \in X} \; h(x) + \sum_{k=1}^{K} \langle y_k^*, x_k^* - x \rangle$$

$$x_k^* = x_0^*, \quad k = 1, \ldots, K.$$

That is, any limit point of Algorithm 2 is a stationary solution of problem (2.2).

3. *If X is a compact set, then the sequence of iterates generated by Algorithm 2 converges to the set of stationary solutions of problem (2.2). That is,*

$$(2.25) \qquad \lim_{t \to \infty} \mathrm{dist}\left((\{x_k^t\}, x_0^t, y^t); Z^* \right) = 0,$$

where Z^* is the set of primal-dual stationary solutions of problem (2.2); $\mathrm{dist}(x; Z^*)$ denotes the distance between a vector x and the set Z^*, i.e.,

$$\mathrm{dist}(x; Z^*) = \min_{\hat{x} \in Z^*} \|x - \hat{x}\|.$$

Proof. We first show part 1 of the theorem. For the essentially cyclic update rule, Lemma 2.2 implies that

$$L(\{x_k^{t+T}\}, x_0^{t+T}; y^{t+T}) - L(\{x_k^t\}, x_0^t; y^t)$$

$$\leq \sum_{i=1}^{T} \sum_{k \neq 0, k \in \mathcal{C}^{t+i}} \left(\frac{L_k^2}{\rho_k} - \frac{\gamma_k(\rho_k)}{2} \right) \|x_k^{t+i} - x_k^{t+i-1}\|^2 - \frac{\gamma}{2} \|x_0^{t+i-1} - x_0^{t+i}\|^2$$

$$= \sum_{i=1}^{T} \sum_{k=1}^{K} \left(\frac{L_k^2}{\rho_k} - \frac{\gamma_k(\rho_k)}{2} \right) \|x_k^{t+i} - x_k^{t+i-1}\|^2 - \frac{\gamma}{2} \|x_0^{t+i-1} - x_0^{t+i}\|^2,$$

where the last equality follows from the fact $x_k^{t+i} = x_k^{t+i-1}$ if $k \notin \mathcal{C}^{t+i}$ and $k \neq 0$. Using the fact that each index in $\{0, \ldots, K\}$ will be updated at least once during $[t, \, t+T]$, as well as Lemma 2.3 and the bounds for ρ_k's in Assumption A2, we have

$$(2.26) \qquad \|x_0^{t+1} - x_0^{t(0)}\| \to 0, \quad \|x_k^{t+1} - x_k^{t(k)}\| \to 0 \quad \forall \; k = 1, \ldots, K.$$

By Lemma 2.1, we further obtain $\|y_k^{t+1} - y_k^{t(k)}\| \to 0$ for all $k = 1, 2, \ldots, K$. In light of the dual update step of Algorithm 2, the fact that $\|y_k^{t+1} - y_k^{t(k)}\| \to 0$ implies that $\|x_k^{t+1} - x_0^{t+1}\| \to 0$.

For the randomized update rule, we can take the conditional expectation (over the choice of the blocks) on both sides of (2.18) and obtain

$$\mathbb{E}\left[L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^t\}, x_0^t; y^t) \mid \{x_k^t\}, x_0^t; y^t \right]$$

$$\leq \mathbb{E}\left[\sum_{k \neq 0, k \in \mathcal{C}^{t+1}} \left(\frac{L_k^2}{\rho_k} - \frac{\gamma_k(\rho_k)}{2} \right) \|x_k^{t+1} - x_k^t\|^2 - \frac{\gamma}{2} \|x_0^{t+1} - x_0^t\|^2 \;\middle|\; \{x_k^t\}, x_0^t; y^t \right]$$

$$\leq \sum_{k=1}^{K} p_k p_0 \left(\frac{L_k^2}{\rho_k} - \frac{\gamma_k(\rho_k)}{2} \right) \|\hat{x}_k^{t+1} - x_k^t\|^2 - p_0 \frac{\gamma}{2} \|\hat{x}_0^{t+1} - x_0^t\|^2$$

$$+ \sum_{k=1}^{K} p_k (1 - p_0) \left(\frac{L_k^2}{\rho_k} - \frac{\gamma_k(\rho_k)}{2} \right) \|\tilde{x}_k^{t+1} - x_k^t\|^2$$

$$\leq p_{\min}^2 \sum_{k=1}^{K} \left(\frac{L_k^2}{\rho_k} - \frac{\gamma_k(\rho_k)}{2} \right) \|\hat{x}_k^{t+1} - x_k^t\|^2 - p_{\min} \frac{\gamma}{2} \|\hat{x}_0^{t+1} - x_0^t\|^2,$$

where in the last two inequalities, we have used the fact that ρ_k's satisfy Assumption A2, hence $\frac{L_k^2}{\rho_k} - \frac{\gamma_k(\rho_k)}{2} < 0$ for all k; the last inequality follows from the fact that $p_k \geq p_{\min}$ for all $k = 0, \ldots, K$. Note that by Lemma 2.3, $L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - \underline{f} \geq 0$ for all t, where $\underline{f}$ is defined in Assumption A3. Then let us substract both sides of the above inequality by $\underline{f}$, and invoke the supermartigale convergence theorem [57, Proposition 4.2]. We conclude that $L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1})$ is convergent a.s. and that

$$(2.27) \qquad \|\hat{x}_0^{t+1} - x_0^t\| \to 0, \quad \|\hat{x}_k^{t+1} - x_k^t\| \to 0 \quad \forall\, k = 1, \ldots, K \quad \text{a.s.}$$

By Lemma 2.1, we further obtain $\|\hat{y}_k^{t+1} - y_k^t\| \to 0$ a.s. and for all $k = 1, 2, \ldots, K$. Finally, from the definition of $\hat{y}^{t+1}$, we see that $\|\hat{y}_k^{t+1} - y_k^t\| \to 0$ a.s. implies that $\|\hat{x}_0^{t+1} - \hat{x}_k^{t+1}\| \to 0$ a.s. for all $k = 1, 2, \ldots, K$.

Next we show part 2 of the theorem. For simplicity, we consider only the essentially cyclic rule as the proof because the randomized rule is similar. We begin by examining the optimality condition for the x_k and x_0 subproblems at iteration $t + 1$. Suppose $k \neq 0$, $k \in \mathcal{C}^{t+1}$; then we have

$$(2.28) \qquad\qquad \nabla g_k(x_k^{t+1}) + y_k^t + \rho_k(x_k^{t+1} - x_0^{t+1}) = 0.$$

Similarly, suppose $0 \in \mathcal{C}^{t+1}$; then there exists an $\eta^{t+1} \in \partial h(x_0^{t+1})$ such that

$$\left\langle x - x_0^{t+1}, \eta^{t+1} - \sum_{k=1}^{K} \left(y_k^t - \rho_k(x_0^{t+1} - x_0^t) \right) \right\rangle \geq 0 \quad \forall\, x \in X.$$

These expressions imply that

$$\nabla g_k(x_k^{t+1}) + y_k^t + \rho_k(x_k^{t+1} - x_0^{t+1}) = 0, \; k \neq 0, \; k \in \mathcal{C}^{t+1},$$

$$h(x) - h(x_0^{t+1}) + \left\langle x - x_0^{t+1}, \sum_{k=1}^{K} \left(-y_k^t + \rho_k(x_0^{t+1} - x_0^t) \right) \right\rangle \geq 0, \; \forall\, x \in X, \; \text{if } 0 \in \mathcal{C}^{t+1}.$$

$$(2.29)$$

Using the definition of the essentially cyclic update rule, we have that for all t

$$\nabla g_k(x_k^{r(k)}) + y_k^{r(k)} = 0, \; \forall\, k \neq 0, \; \text{for some } r(k) \in [t, \; t + T],$$

$$(2.30) \quad h(x) - h(x_0^{r(0)}) + \left\langle x - x_0^{r(0)}, \sum_{k=1}^{K} \left(-y_k^{r(0)-1} + \rho_k(x_0^{r(0)} - x_k^{r(0)-1}) \right) \right\rangle \geq 0,$$

$$\forall\, x \in X, \; \text{for some } r(0) \in [t, \; t + T].$$

Note that T is finite and that $\|x_k^{t+1} - x_k^t\| \to 0$, $\|x_0^{t+1} - x_0^t\| \to 0$, and $\|y_k^{t+1} - y_k^t\| \to 0$, and we have

$$\|x_k^{r(k)} - x_k^{t+1}\| \to 0 \quad \forall\, k, \quad \|x_0^{r(0)} - x_0^{t+1}\| \to 0,$$

$$(2.31) \qquad \|y_k^{t+1} - y_k^{r(k)}\| \to 0, \quad \|y_k^{t+1} - y_k^{r(0)-1}\| \to 0 \quad \forall\, k.$$

Using this result, taking limit for (2.30), and using the fact that $\|x_k^{t+1} - x_k^t\| \to 0$, $x_0^{t+1} \to x_0^*$, $x_k^{t+1} \to x_k^*$, $y_k^{t+1} \to y_k^*$ for all k, we have

$$\nabla g_k(x_k^*) + y_k^* = 0, \ k = 1, \ldots, K,$$

$$(2.32) \qquad h(x) - h(x_0^*) + \sum_{k=1}^{K} \left\langle x - x_0^*, -y_k^* \right\rangle \geq 0 \quad \forall x \in X.$$

Due to the fact that $\|y_k^{t+1} - y_k^t\| \to 0$ for all k, we have that the primal feasibility is achieved in the limit, i.e.,

$$(2.33) \qquad x_k^* = x_0^* \quad \forall\, k = 1, \ldots, K.$$

This set of equalities together with (2.32) imply

$$(2.34) \qquad h(x) + \sum_{k=1}^{K} \left\langle x_k^* - x, y_k^* \right\rangle - \left(h(x_0^*) + \sum_{k=1}^{K} \left\langle x_k^* - x_0^*, y_k^* \right\rangle \right) \geq 0 \quad \forall x \in X.$$

This concludes the proof of part 2.

To prove part 3, we first show that there exists a limit point for each of the sequences $\{x_k^t\}$, $\{x_0^t\}$, and $\{y^t\}$. Let us consider only the essentially cyclic rule. Due to the compactness assumption of X, it is obvious that $\{x_0^t\}$ must have a limit point. Also by a similar argument leading to (2.26), we see that $\|x_k^t - x_0^t\| \to 0$; thus for each k, x_k^t must also lie in a compact set and thus have a limit point. Note that the Lipschitz continuity of ∇g_k combined with the compactness of the set X implies that the set $\{\nabla g_k(x) \mid x \in X\}$ is bounded; therefore $\{\nabla g_k(x_k^t)\}$ is a bounded sequence. Using (2.17), we conclude that $\{y_k^t\}$ is also a bounded sequence and therefore must have at least one limit point.

We prove part 3 by contradiction. Because the feasible set is compact, then $\{x_k^t\}$ lies in a compact set. From the argument in the previous part it is easy to see that $\{x_0^t\}$, $\{y^t\}$ also lie in some compact sets. Then every subsequence will have a limit point. Suppose that there exists a subsequence $\{x_k^{t_j}\}$, $x_0^{t_j}$, and $\{y^{t_j}\}$ such that

$$(2.35) \qquad (\{x_k^{t_j}\}, x_0^{t_j}, y^{t_j}) \to (\{\hat{x}_k\}, \hat{x}_0, \hat{y}),$$

where $(\{\hat{x}_k\}, \hat{x}_0, \hat{y})$ is some limit point, and by part 2, we have $(\hat{x}_k, \hat{x}_0, \hat{y}) \in Z^*$. By further restricting to a subsequence if necessary, we can assume that $(\hat{x}_k, \hat{x}_0, \hat{y})$ is the unique limit point.

Suppose that this sequence does not converge to the set of stationary solutions, i.e.,

$$(2.36) \qquad \lim_{j \to \infty} \mathrm{dist}\left((\{x_k^{t_j}\}, x_0^{t_j}, y^{t_j}); Z^* \right) = \gamma > 0.$$

Then it follows that there exists some $J(\gamma) > 0$ such that

$$\|(\{x_k^{t_j}\}, x_0^{t_j}, y^{t_j}) - (\{\hat{x}_k\}, \hat{x}_0, \hat{y})\| \leq \gamma/2 \quad \forall\, j \geq J(\gamma).$$

By the definition of the distance function we have

$$\mathrm{dist}\left((\{x_k^{t_j}\}, x_0^{t_j}, y^{t_j}); Z^* \right) \leq \mathrm{dist}\left((\{x_k^{t_j}\}, x_0^{t_j}, y^{t_j}), (\{\hat{x}_k\}, \hat{x}_0, \hat{y}) \right).$$

Combining the above two inequalities we must have

$$\text{dist}\left(\left(\{x_k^{t_j}\}, x_0^{t_j}, y^{t_j}\right); Z^*\right) \leq \gamma/2 \quad \forall \, t_j \geq T_j(\gamma).$$

This contradicts to (2.36). The desired result is proven. $\quad\square$

The analysis presented above is different from the conventional analysis of the ADMM algorithm where the main effort is to bound the distance between the current iterate and the optimal solution set. The above analysis is partly motivated by our previous analysis of the convergence of ADMM for multiblock convex problems, where the progress of the algorithm is measured by the combined decrease of certain primal and dual gaps; see [27, Theorem 3.1]. Nevertheless, the nonconvexity of the problem makes it difficult to estimate either the primal or the dual optimality gaps. Therefore we choose to use the decrease of the augmented Lagrangian as a measure of the progress of the algorithm.

Next we analyze the iteration complexity of the vanilla ADMM (i.e., Algorithm 1). To state our result, let us define the *proximal gradient* of the augmented Lagrangian function as

$$(2.37) \qquad \tilde{\nabla} L(\{x_k\}, x_0, y) = \begin{bmatrix} x_0 - \text{prox}_h\left[x_0 - \nabla_{x_0}(L(\{x_k\}, x_0, y) - h(x_0))\right] \\ \nabla_{x_1} L(\{x_k\}, x_0, y) \\ \vdots \\ \nabla_{x_K} L(\{x_k\}, x_0, y) \end{bmatrix},$$

where $\text{prox}_h[z] := \arg\min_x h(x) + \frac{1}{2}\|x - z\|^2$ is the proximity operator. We will use the following quantity to measure the progress of the algorithm:

$$P(\{x_k^t\}, x^t, y^t) := \|\tilde{\nabla} L(\{x_k^t\}, x_0^t, y^t)\|^2 + \sum_{k=1}^{K} \|x_k^t - x_0^t\|^2.$$

It can be verified that if $P(\{x_k^t\}, x^t, y^t) \to 0$, then a stationary solution of the problem (2.2) is obtained. We have the following iteration complexity result.

THEOREM 2.5. *Suppose Assumption A is satisfied. Let $T(\epsilon)$ denote an iteration index in which the following inequality is achieved:*

$$T(\epsilon) := \min\left\{t \mid P(\{x_k^t\}, x^t, y^t) \leq \epsilon, t \geq 0\right\}$$

for some $\epsilon > 0$. Then there exists some constant $C > 0$ such that

$$(2.38) \qquad \epsilon \leq \frac{C(L(\{x_k^1\}, x_0^1, y^1) - \underline{f})}{T(\epsilon)},$$

where $\underline{f}$ is defined in Assumption A3.

Proof. We first show that there exists a constant $\sigma_1 > 0$ such that

$$(2.39) \qquad \|\tilde{\nabla} L(\{x_k^t\}, x_0^t, y^t)\| \leq \sigma_1\left(\|x_0^{t+1} - x_0^t\| + \sum_{k=1}^{K} \|x_k^{t+1} - x_k^t\|\right) \quad \forall \, r \geq 1.$$

This proof follows similar steps of [27, Lemma 2.5]. From the optimality condition of the x_0 update step (2.10) we have

$$x_0^{t+1} = \text{prox}_h\left[x_0^{t+1} - \sum_{k=1}^{K} \rho_k\left(x_0^{t+1} - x_k^t - \frac{y_k^t}{\rho_k}\right)\right].$$

This implies that

$$\|x_0^t - \text{prox}_h \left[x_0^t - \nabla_{x_0}(L(\{x_k^t\}, x_0^t, y^t) - h(x_0^t)) \right] \|$$

$$= \left\| x_0^t - x_0^{t+1} + x_0^{t+1} - \text{prox}_h \left[x_0^t - \sum_{k=1}^{K} \rho_k(x_0^t - x_k^t - \frac{y_k^t}{\rho_k}) \right] \right\|$$

$$\leq \|x_0^t - x_0^{t+1}\| + \left\| \text{prox}_h \left[x_0^{t+1} - \sum_{k=1}^{K} \rho_k \left(x_0^{t+1} - x_k^t - \frac{y_k^t}{\rho_k} \right) \right] \right.$$

$$\left. - \text{prox}_h \left[x_0^t - \sum_{k=1}^{K} \rho_k(x_0^t - x_k^t - \frac{y_k^t}{\rho_k}) \right] \right\|$$

$$(2.40) \qquad \leq 2\|x_0^{t+1} - x_0^t\| + \sum_{k=1}^{K} \rho_k \|x_0^t - x_0^{t+1}\|,$$

where in the last inequality we have used the nonexpansiveness of the proximity operator.

Similarly, the optimality condition of the x_k subproblem is given by

$$\nabla g_k(x_k^{t+1}) + \rho_k \left(x_k^{t+1} - x_0^{t+1} + \frac{y_k^t}{\rho_k} \right) = 0.$$

Therefore we have

$$\|\nabla_{x_k} L(\{x_k^t\}, x_0^t, y^t)\|$$

$$= \left\| \nabla g_k(x_k^t) + \rho_k \left(x_k^t - x_0^t + \frac{y_k^t}{\rho_k} \right) \right\|$$

$$= \left\| \left(\nabla g_k(x_k^t) + \rho_k \left(x_k^t - x_0^t + \frac{y_k^t}{\rho_k} \right) \right) - \left(\nabla g_k(x_k^{t+1}) + \rho_k \left(x_k^{t+1} - x_0^{t+1} + \frac{y_k^t}{\rho_k} \right) \right) \right\|$$

$$\leq (L_k + \rho_k)\|x_k^t - x_k^{t+1}\| + \rho_k\|x_0^t - x_0^{t+1}\|.$$

$$(2.41)$$

Therefore, combining (2.40) and (2.41), we have

$$(2.42)$$

$$\|\tilde{\nabla}L(\{x_k^t\}, x_0^t, y^t)\| \leq \left(2 + \sum_{k=1}^{K} 2\rho_k \right) \|x_0^t - x_0^{t+1}\| + \sum_{k=1}^{K}(L_k + \rho_k)\|x_k^t - x_k^{t+1}\|.$$

By taking $\sigma_1 = \max\{(2 + \sum_{k=1}^{K} 2\rho_k), L_1 + \rho_1, \ldots, L_K + \rho_K\}$, (2.39) is proved.

According to Lemma 2.1, we have

$$(2.43) \qquad \sum_{k=1}^{K} \|x_k^{t+1} - x_0^{t+1}\| = \sum_{k=1}^{K} \frac{1}{\rho_k}\|y_k^{t+1} - y_k^t\| \leq \sum_{k=1}^{K} \frac{L_k}{\rho_k}\|x_k^{t+1} - x_k^t\|.$$

The inequalities (2.42)–(2.43) imply that for some $\sigma_3 > 0$

$$\sum_{k=1}^{K} \|x_k^t - x_0^t\|^2 + \|\tilde{\nabla} L(\{x_k^t\}, x_0^t, y^t)\|^2$$

(2.44)
$$\leq \sigma_3 \left(\|x_0^t - x_0^{t+1}\|^2 + \sum_{k=1}^{K} \|x_k^t - x_k^{t+1}\|^2 \right).$$

According to Lemma 2.2, there exists a constant $\sigma_2 = \min\{\{\frac{\gamma_k(\rho_k)}{2} - \frac{L_k^2}{\rho_k}\}_{k=1}^{K}, \frac{\gamma}{2}\}$ such that

$$L(\{x_k^t\}, x_0^t; y^t) - L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1})$$

(2.45)
$$\geq \sigma_2 \left(\sum_{k=1}^{K} \|x_k^{t+1} - x_k^t\|^2 + \|x_0^{t+1} - x_0^t\|^2 \right).$$

Combining (2.44) and (2.45) we have

$$\sum_{k=1}^{K} \|x_k^t - x_0^t\|^2 + \|\tilde{\nabla} L(\{x_k^t\}, x_0^t, y^t)\|^2$$
$$\leq \frac{\sigma_3}{\sigma_2} \left(L(\{x_k^t\}, x_0^t; y^t) - L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) \right).$$

Summing both sides of the above inequality over $t = 1, \ldots, r$, we have

$$\sum_{t=1}^{r} \sum_{k=1}^{K} \|x_k^t - x_0^t\|^2 + \|\tilde{\nabla} L(\{x_k^t\}, x_0^t, y^t)\|^2$$
$$\leq \frac{\sigma_3}{\sigma_2} \left(L(\{x_k^1\}, x_0^1; y^1) - L(\{x_k^{r+1}\}, x_0^{r+1}; y^{r+1}) \right)$$
$$\leq \frac{\sigma_3}{\sigma_2} \left(L(\{x_k^1\}, x_0^1; y^1) - \underline{f} \right),$$

where in the last inequality we have used the fact that $L(\{x_k^{r+1}\}, x_0^{r+1}; y^{r+1})$ is decreasing and lower bounded by $\underline{f}$ (cf. Lemmas 2.2–2.3).

By utilizing the definition of $T(\epsilon)$ and $P(\{x_k^t\}, x^t, y^t)$, the above inequality becomes

(2.46)
$$T(\epsilon)\epsilon \leq \frac{\sigma_3}{\sigma_2} \left(L(\{x_k^1\}, x_0^1; y^1) - \underline{f} \right).$$

By dividing both sides by $T(\epsilon)$, and by setting $C = \sigma_3/\sigma_2$, the desired result is obtained. $\square$

2.3. The proximal ADMM. One potential limitation of Algorithms 1 and 2 is the requirement that each subproblem (2.11) needs to be solved *exactly*, while in certain practical applications cheap iterations are preferred. In this section, we consider an important extension of Algorithms 1–2 in which the above restriction is removed. The main idea is to take a proximal step instead of minimizing the augmented Lagrangian function exactly with respect to each variable block. Like in the previous section, we will analyze a generalized version, termed the *flexible* proximal ADMM, where there is more freedom in choosing the update schedules.

Algorithm 3. A flexible proximal ADMM for problem (2.2).

At each iteration $t + 1$, compute

(2.47) $$x_0^{t+1} = \operatorname*{argmin}_{x \in X} \ L(\{x_k^t\}, x_0; y^t).$$

Pick a set $\mathcal{C}^{t+1} \subseteq \{1, \ldots, K\}$.
If $k \in \mathcal{C}^{t+1}$, update x_k by solving

(2.48)
$$x_k^{t+1} = \operatorname*{argmin}_{x_k} \langle \nabla g_k(x_0^{t+1}), x_k - x_0^{t+1} \rangle + \langle y_k^t, x_k - x_0^{t+1} \rangle + \frac{\rho_k + L_k}{2} \|x_k - x_0^{t+1}\|^2.$$

Update the dual variable:

(2.49) $$y_k^{t+1} = y_k^t + \rho_k \left(x_k^{t+1} - x_0^{t+1} \right).$$

Else let $x_k^{t+1} = x_k^t$, $y_k^{t+1} = y_k^t$.

Notice that the x_k update step is different from the conventional proximal update (e.g., [8]). In particular, the linearization is done with respect to x_0^{t+1} instead of x_k^t computed in the previous iteration. This modification is instrumental in the convergence analysis of Algorithm 3.

Here we use the *period-T essentially cyclic rule* to decide the set $\mathcal{C}^{t+1}$ at each iteration. We note that there is a slight difference of the update schedule used in Algorithm 3 and in Algorithm 2. In Algorithm 3, the block variable x_0 is updated *in every iteration*, while in Algorithm 2 the update of x_0 is also governed by block selection rules.

Now we begin analyzing Algorithm 3. We make the following assumptions in this section (in addition to Assumptions A1 and A3).

Assumption B. For all k, the penalty parameter ρ_k is chosen large enough such that

(2.50) $$\alpha_k := \frac{\rho_k - 7L_k}{2} - \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 2L_k^2 > 0,$$

(2.51) $$\beta_k := \frac{\rho_k}{2} - T^2 \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 8L_k^2 > 0,$$

(2.52) $$\rho_k \geq 5L_k, \ k = 1, \ldots, K.$$

Again let $t(k)$ denote the last iteration that x_k is updated before $t + 1$, i.e.,

(2.53) $$t(k) = \max \{r \mid r \leq t, k \in \mathcal{C}^r\}, \ k = 1, \ldots, K.$$

Note that we do not need $t(0)$ anymore since x_0 is updated in every iteration. Clearly, we have $x_k^t = x_k^{t(k)}$ and as a result, $y_k^t = y_k^{t(k)}$. We have the following result.

LEMMA 2.6. *Suppose Assumption* B *and Assumptions* A1, A3 *are satisfied. Then for Algorithm* 3, *the following is true for the essentially cyclic block selection rule:*

(2.54) $$2L_k^2(4\|x_0^{t+1} - x_0^{t(k)}\|^2 + \|x_k^{t+1} - x_k^t\|^2) \geq \|y_k^{t+1} - y_k^t\|^2, \ k = 1, \ldots, K.$$

Proof. Suppose $k \notin \mathcal{C}^{t+1}$; then the inequality is trivially true, as $y_k^{t+1} = y_k^t$. For any $k \in \mathcal{C}^{t+1}$, we observe from the update of x_k step (2.48) that

$$(2.55) \qquad \nabla g_k(x^{t+1}) + y_k^t + (\rho_k + L_k)(x_k^{t+1} - x_0^{t+1}) = 0, \ k \in \mathcal{C}^{t+1},$$

is true, or equivalently

$$(2.56) \qquad \nabla g_k(x^{t+1}) + L_k(x_k^{t+1} - x_0^{t+1}) = -y_k^{t+1}, \ k \in \mathcal{C}^{t+1}.$$

Therefore we have for all $k \in \mathcal{C}^{t+1}$

$$
\begin{aligned}
\|y_k^{t+1} - y_k^t\| &= \|y_k^{t+1} - y_k^{t(k)}\| \\
&= \|\nabla g_k(x_0^{t+1}) - \nabla g_k(x_0^{t(k)}) + L_k(x_k^{t+1} - x_0^{t+1}) - L_k(x_k^{t(k)} - x_0^{t(k)})\| \\
&= \|\nabla g_k(x_0^{t+1}) - \nabla g_k(x_0^{t(k)}) + L_k(x_k^{t+1} - x_0^{t+1}) - L_k(x_k^t - x_0^{t(k)})\| \\
&\le L_k(2\|x_0^{t+1} - x_0^{t(k)}\| + \|x_k^{t+1} - x_k^t\|),
\end{aligned}
$$

where the last step follows from the triangular inequality and the fact $x_k^t = x_k^{t(k)}$ (cf. the definition of $t(k)$). The above result further implies that

$$(2.57) \qquad 2L_k^2(4\|x_0^{t+1} - x_0^{t(k)}\|^2 + \|x_k^{t+1} - x_k^t\|^2) \ge \|y_k^{t+1} - y_k^t\|^2, \ k = 1, \ldots, K,$$

which is the desired result. $\square$

Next, we upper bound the successive difference of the augmented Lagrangian. To this end, let us define the following functions:

$$
\begin{aligned}
\ell_k(x_k; x_0^{t+1}, y^t) &= g_k(x_k) + \langle y_k^t, x_k - x_0^{t+1} \rangle + \frac{\rho_k}{2}\|x_k - x_0^{t+1}\|^2 \\
u_k(x_k; x_0^{t+1}, y^t) &= g_k(x_0^{t+1}) + \langle \nabla g_k(x_0^{t+1}), x_k - x_0^{t+1} \rangle \\
&\quad + \langle y_k^t, x_k - x_0^{t+1} \rangle + \frac{\rho_k + L_k}{2}\|x_k - x_0^{t+1}\|^2.
\end{aligned}
$$

Using these short-hand definitions, we have

$$(2.58) \qquad L(\{x_k^{t+1}\}, x_0^{t+1}; y^t) = \sum_{k=1}^{K} \ell_k(x_k^{t+1}; x_0^{t+1}, y^t)$$

$$(2.59) \qquad x_k^{t+1} = \arg\min_{x_k} u_k(x_k; x_0^{t+1}, y^t) \quad \forall \ k \in \mathcal{C}^{t+1}.$$

The lemma below bounds the difference between $\ell_k(x_k^{t+1}; x_0^{t+1}, y^t)$ and $\ell_k(x_k^t; x_0^{t+1}, y^t)$.

LEMMA 2.7. *Suppose Assumption* A1 *is satisfied. Let* $\{x_k^t, x_0^t, y^t\}$ *be generated by Algorithm* 3 *with the essential cyclic block update rule. Then we have the following:*

$$
\begin{aligned}
&\ell_k(x_k^{t+1}; x_0^{t+1}, y^t) - \ell_k(x_k^t; x_0^{t+1}, y^t) \\
(2.60) \qquad &\le -\frac{\rho_k - 7L_k}{2}\|x_k^{t+1} - x_k^t\|^2 + \frac{4L_k}{\rho_k^2}\|y_k^{t+1} - y_k^t\|^2, \quad k = 1, \ldots, K.
\end{aligned}
$$

Proof. When $k \notin \mathcal{C}^{t+1}$, the inequality is trivially true. We focus on the case $k \in \mathcal{C}^{t+1}$. From the definition of $\ell_k(\cdot)$ and $u_k(\cdot)$ we have the following:

$$(2.61) \qquad \ell_k(x_k; x_0^{t+1}, y^t) \le u_k(x_k; x_0^{t+1}, y^t) \quad \forall \ x_k, \ k = 1, \ldots, K.$$

Observe that when $k \in \mathcal{C}^{t+1}$, x_k^{t+1} is generated according to (2.59). Due to the strong convexity of $u_k(x_k; x_0^{t+1}, y^t)$ with respect to x_k, we have

$$(2.62) \quad u_k(x_k^{t+1}; x_0^{t+1}, y^t) - u_k(x_k^t; x_0^{t+1}, y^t) \leq -\frac{\rho_k + L_k}{2}\|x_k^t - x_k^{t+1}\|^2 \quad \forall \, k \in \mathcal{C}^{t+1}.$$

Further, we have the following series of inequalities:

$$u_k(x_k^t; x_0^{t+1}, y^t) - \ell_k(x_k^t; x_0^{t+1}, y^t)$$
$$= g_k(x_0^{t+1}) + \langle \nabla g_k(x_0^{t+1}), x_k^t - x_0^{t+1} \rangle + \langle y_k^t, x_k^t - x_0^{t+1} \rangle + \frac{\rho_k + L_k}{2}\|x_k^t - x_0^{t+1}\|^2$$
$$\quad - \left(g_k(x_k^t) + \langle y_k^t, x_k^t - x_0^{t+1} \rangle + \frac{\rho_k}{2}\|x_k^t - x_0^{t+1}\|^2 \right)$$
$$= g_k(x_0^{t+1}) - g_k(x_k^t) + \langle \nabla g_k(x_0^{t+1}), x_k^t - x_0^{t+1} \rangle + \frac{L_k}{2}\|x_k^t - x_0^{t+1}\|^2$$
$$\leq \langle \nabla g_k(x_0^{t+1}) - \nabla g_k(x_k^t), x_k^t - x_0^{t+1} \rangle + L_k\|x_k^t - x_0^{t+1}\|^2$$
$$\leq 2L_k\|x_k^t - x_0^{t+1}\|^2 \leq 4L_k \left(\|x_k^t - x_k^{t+1}\|^2 + \|x_k^{t+1} - x_0^{t+1}\|^2 \right),$$
(2.63)

where the first two inequalities follow from Assumption A1. Combining (2.61)–(2.63) we obtain

$$\ell_k(x_k^{t+1}; x_0^{t+1}, y^t) - \ell_k(x_k^t; x_0^{t+1}, y^t)$$
$$\leq u_k(x_k^{t+1}; x_0^{t+1}, y^t) - u_k(x_k^t; x_0^{t+1}, y^t) + u_k(x_k^t; x_0^{t+1}, y^t) - \ell_k(x_k^t; x_0^{t+1}, y^t)$$
$$\leq -\frac{\rho_k - 7L_k}{2}\|x_k^t - x_k^{t+1}\|^2 + 4L_k\|x_k^{t+1} - x_0^{t+1}\|^2$$
$$= -\frac{\rho_k - 7L_k}{2}\|x_k^t - x_k^{t+1}\|^2 + \frac{4L_k}{\rho_k^2}\|y_k^{t+1} - y_k^t\|^2 \quad \forall \, k \in \mathcal{C}^{t+1}.$$

The desired result then follows. □

Next, we bound the difference of the augmented Lagrangian function values.

LEMMA 2.8. *Assume the same setup as in Lemma* 2.7. *Then we have*

$$L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^1\}, x_0^1; y^1)$$
$$(2.64) \qquad \leq -\sum_{i=1}^t \sum_{k=1}^K \alpha_k\|x_k^{i+1} - x_k^i\|^2 - \sum_{i=1}^t \sum_{k=1}^K \beta_k\|x_0^{i+1} - x_0^i\|^2,$$

where β_k and α_k are the positive constants defined in (2.50) *and* (2.51).

Proof. We first bound the successive difference $L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1})$ $- L(\{x_k^t\}, x_0^t; y^t)$. Again we decompose it as in (2.19) and bound the resulting two differences separately.

The first term in (2.19) can be again expressed as

$$L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^{t+1}\}, x_0^{t+1}; y^t) = \sum_{k=1}^K \frac{1}{\rho_k}\|y_k^{t+1} - y_k^t\|^2.$$

To bound the second term in (2.19), we use Lemma 2.7. We use an argument similar to the proof of (2.21) to obtain

$$L(\{x_k^{t+1}\}, x_0^{t+1}; y^t) - L(\{x_k^t\}, x_0^t; y^t)$$

$$= L(\{x_k^{t+1}\}, x_0^{t+1}; y^t) - L(\{x_k^t\}, x_0^{t+1}; y^t) + L(\{x_k^t\}, x_0^{t+1}; y^t) - L(\{x_k^t\}, x_0^t; y^t)$$

$$= \sum_{k=1}^{K} \left(\ell_k(x_k^{t+1}; x_0^{t+1}, y^t) - \ell_k(x_k^t; x_0^{t+1}, y^t) \right) + L(\{x_k^t\}, x_0^{t+1}; y^t) - L(\{x_k^t\}, x_0^t; y^t)$$

$$\leq -\sum_{k=1}^{K} \left(\frac{\rho_k - 7L_k}{2} \|x_k^{t+1} - x_k^t\|^2 - \frac{4L_k}{\rho_k^2} \|y_k^{t+1} - y_k^t\|^2 \right) - \frac{\gamma}{2} \|x_0^{t+1} - x_0^t\|^2,$$

(2.65)

where the last inequality follows from Lemma 2.7 and the strong convexity of $L(\{x_k^t\}, x_0; y^t)$ with respect to the variable x (with modulus $\gamma = \sum_{k=1}^{K} \rho_k$) at $x_0 = x_0^{t+1}$.

Combining the above two inequalities, we obtain

$$L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^t\}, x_0^t; y^t)$$

$$\leq \sum_{k=1}^{K} \left(-\frac{\rho_k - 7L_k}{2} \|x_k^{t+1} - x_k^t\|^2 + \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) \|y_k^{t+1} - y_k^t\|^2 \right) - \frac{\gamma}{2} \|x_0^{t+1} - x_0^t\|^2$$

$$\overset{(a)}{\leq} \sum_{k=1}^{K} \Bigg(-\frac{\rho_k - 7L_k}{2} \|x_k^{t+1} - x_k^t\|^2$$

$$+ \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 2L_k^2 (4\|x_0^{t+1} - x_0^{t(k)}\|^2 + \|x_k^{t+1} - x_k^t\|^2) \Bigg)$$

$$- \frac{\gamma}{2} \|x_0^{t+1} - x_0^t\|^2$$

$$\overset{(b)}{=} -\sum_{k=1}^{K} \left(\frac{\rho_k - 7L_k}{2} - \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 2L_k^2 \right) \|x_k^{t+1} - x_k^t\|^2 - \sum_{k=1}^{K} \left(\frac{\rho_k}{2} \right) \|x_0^{t+1} - x_0^t\|^2$$

$$+ \sum_{k=1}^{K} \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 8L_k^2 \|x_0^{t(k)} - x_0^{t+1}\|^2$$

$$\leq -\sum_{k=1}^{K} \left(\frac{\rho_k - 7L_k}{2} - \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 2L_k^2 \right) \|x_k^{t+1} - x_k^t\|^2 - \sum_{k=1}^{K} \left(\frac{\rho_k}{2} \right) \|x_0^{t+1} - x_0^t\|^2$$

(2.66)

$$+ \sum_{k=1}^{K} T \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 8L_k^2 \sum_{i=0}^{\min\{T-1, t-1\}} \|x_0^{t-i+1} - x_0^{t-i}\|^2,$$

where in (a) we have used (2.54); in (b) we have used the fact that $\gamma = \sum_{k=1}^{K} \rho_k$; in the last inequality we have used the definition of the period-T essentially cyclic update rule which implies that

$$\|x_0^{t+1} - x_0^{t(k)}\| \leq \sum_{i=0}^{\min\{T-1, t-1\}} \|x_0^{t-i+1} - x_0^{t-i}\|$$

(2.67) $$\implies \|x_0^{t+1} - x_0^{t(k)}\|^2 \leq T \sum_{i=0}^{\min\{T-1, t-1\}} \|x_0^{t-i+1} - x_0^{t-i}\|^2.$$

Then for any given t, the difference $L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^1\}, x_0^1; y^1)$ is obtained by summing (2.66) over all iterations. Specifically, we obtain

$$L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^1\}, x_0^1; y^1)$$

$$\leq -\sum_{i=1}^t \sum_{k=1}^K \left(\frac{\rho_k - 7L_k}{2} - \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 2L_k^2 \right) \|x_k^{i+1} - x_k^i\|^2$$

$$- \sum_{i=1}^t \sum_{k=1}^K \left(\frac{\rho_k}{2} - T^2 \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 8L_k^2 \right) \|x_0^{i+1} - x_0^i\|^2$$

$$= -\sum_{i=1}^t \sum_{k=1}^K \alpha_k \|x_k^{i+1} - x_k^i\|^2 - \sum_{i=1}^t \sum_{k=1}^K \beta_k \|x_0^{i+1} - x_0^i\|^2.$$

This completes the proof. ☐

We conclude that to make the rhs of (2.64) negative at each iteration, it is sufficient to require that $\alpha_k > 0$ and $\beta_k > 0$ for all k, or more specifically,

(2.68)
$$\frac{\rho_k - 7L_k}{2} - \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 2L_k^2 > 0, \ k = 1, \dots, K,$$

$$\frac{\rho_k}{2} - T^2 \left(\frac{4L_k}{\rho_k^2} + \frac{1}{\rho_k} \right) 8L_k^2 > 0, \ k = 1, \dots, K.$$

Note that one can always find a set of ρ_k's large enough such that the above condition is satisfied.

Next we show that $L(\{x_k^t\}, x_0^t; y^t)$ is convergent.

LEMMA 2.9. *Suppose Assumptions* A1, A3 *and Assumption* B *are satisfied. Then Algorithm* 3 *with the period-T essentially cyclic update rule generates a sequence of augmented Lagrangian, whose limit exists and is bounded below by* $\underline{f}$.

Proof. Observe that the augmented Lagrangian can be expressed as

$$L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1})$$

$$= h(x_0^{t+1}) + \sum_{k=1}^K \left(g_k(x_k^{t+1}) + \langle y_k^{t+1}, x_k^{t+1} - x_0^{t+1} \rangle + \frac{\rho_k}{2} \|x_k^{t+1} - x_0^{t+1}\|^2 \right)$$

$$\overset{(a)}{=} h(x_0^{t+1}) + \sum_{k=1}^K \left(g_k(x_k^{t+1}) + \langle \nabla g_k(x_0^{t+1}) + L_k(x_k^{t+1} - x_0^{t+1}), x_0^{t+1} - x_k^{t+1} \rangle \right.$$

$$\left. + \frac{\rho_k}{2} \|x_k^{t+1} - x_0^{t+1}\|^2 \right)$$

$$= h(x_0^{t+1}) + \sum_{k=1}^K \left(g_k(x_k^{t+1}) + \langle \nabla g_k(x_0^{t+1}), x_0^{t+1} - x_k^{t+1} \rangle + \frac{\rho_k - 2L_k}{2} \|x_k^{t+1} - x_0^{t+1}\|^2 \right)$$

$$\overset{(b)}{\geq} h(x_0^{t+1}) + \sum_{k=1}^K \left(g_k(x_0^{t+1}) + \frac{\rho_k - 5L_k}{2} \|x_k^{t+1} - x_0^{t+1}\|^2 \right)$$

$$= f(x_0^{t+1}) + \sum_{k=1}^K \frac{\rho_k - 5L_k}{2} \|x_k^{t+1} - x_0^{t+1}\|^2,$$

(2.69)

where (a) is from (2.56); (b) is due to the following inequalities:

$$g_k(x_0^{t+1}) \le g_k(x_k^{t+1}) + \langle \nabla g_k(x_k^{t+1}), x_0^{t+1} - x_k^{t+1} \rangle + \frac{L_k}{2}\|x_k^{t+1} - x_0^{t+1}\|^2$$

$$= g_k(x_k^{t+1}) + \langle \nabla g_k(x_k^{t+1}) - \nabla g_k(x_0^{t+1}), x_0^{t+1} - x_k^{t+1} \rangle$$

$$+ \langle \nabla g_k(x_0^{t+1}), x_0^{t+1} - x_k^{t+1} \rangle + \frac{L_k}{2}\|x_k^{t+1} - x_0^{t+1}\|^2$$

$$\le g_k(x_k^{t+1}) + \langle \nabla g_k(x_0^{t+1}), x_0^{t+1} - x_k^{t+1} \rangle + \frac{3L_k}{2}\|x_k^{t+1} - x_0^{t+1}\|^2.$$

Clearly, combining the inequality (2.69) with Assumption B and A3 yields that $L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1})$ is lower bounded. It follows from Lemma 2.8 that whenever the penalty parameter ρ_k's are chosen sufficiently large (as per Assumption B), $L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1})$ will monotonically decrease and is convergent. This completes the proof. □

Using Lemmas 2.6–2.9, we arrive at the following convergence result. The proof is similar to Theorem 2.4 and is thus omitted.

THEOREM 2.10. *Suppose that Assumptions* A1, A3, *and* B *hold. Then the following is true for Algorithm* 3*:*
1. *We have* $\lim_{t\to\infty} \|x_0^{t+1} - x_k^{t+1}\| = 0$, $k = 1, \dots, K$.
2. *Let* $(\{x_k^*\}, x_0^*, y^*)$ *denote any limit point of the sequence* $\{\{x_k^{t+1}\}, x_0^{t+1}, y^{t+1}\}$ *generated by Algorithm* 3 *with period-T essentially cyclic block update rule. Then* $(\{x_k^*\}, x_0^*, y^*)$ *is a stationary solution of problem* (2.2).
3. *If* X *is a compact set, then Algorithm* 3 *with period-T essentially cyclic block update rule converges to the set of stationary solutions of problem* (2.2). *That is, the following is true:*

$$(2.70) \qquad \lim_{t\to\infty} \text{dist}\left((\{x_k^t\}, x_0^t, y^t); Z^*\right) = 0,$$

where Z^* *is the set of primal-dual stationary solutions of problem* (2.2).

3. The nonconvex sharing problem. Consider the following well-known sharing problem (see, e.g., [8, section 7.3] for motivation):

$$(3.1) \qquad \min \quad f(x_1, \dots, x_K) := \sum_{k=1}^{K} g_k(x_k) + \ell\left(\sum_{k=1}^{K} A_k x_k\right)$$

$$\text{s.t.} \quad x_k \in X_k, \; k = 1, \dots, K,$$

where $x_k \in \mathbb{R}^{N_k}$ is the variable associated with a given agent k, and $A_k \in \mathbb{R}^{M \times N_k}$ is some data matrix. The variables are coupled through the function $\ell(\cdot)$.

To facilitate distributed computation, this problem can be equivalently formulated into a linearly constrained problem by introducing an additional variable $x_0 \in \mathbb{R}^M$:

$$(3.2) \qquad \min \quad \sum_{k=1}^{K} g_k(x_k) + \ell(x_0)$$

$$\text{s.t.} \quad \sum_{k=1}^{K} A_k x_k = x_0, \quad x_k \in X_k, \; k = 1, \dots, K.$$

The augmented Lagrangian for this problem is given by

$$(3.3)$$

$$L(\{x_k\}, x_0; y) = \sum_{k=1}^{K} g_k(x_k) + \ell(x_0) + \left\langle x_0 - \sum_{k=1}^{K} A_k x_k, y \right\rangle + \frac{\rho}{2}\left\|x_0 - \sum_{k=1}^{K} A_k x_k\right\|^2.$$

Note that we have chosen a special reformulation in (3.2): a *single* variable x_0 is introduced which leads to a problem with a *single* linear constraint. Applying the classical ADMM to this reformulation leads to a *multiblock* ADMM algorithm in which $K+1$ block variables $(\{x_k\}_{k=1}^K, x_0)$ are updated sequentially. As mentioned in the introduction, even in the case where the objective is convex, it is not known whether the multiblock ADMM converges in this case. Variants of the multiblock ADMM have been proposed in the literature to solve this type of multiblock problem; see recent developments in [26, 27, 28, 29, 30] and the references therein.

In this section, we show that the classical ADMM, together with several of its extensions using different block selection rules, converges even when the objective function is nonconvex. The main assumptions for convergence are that the penalty parameter ρ is large enough and that the coupling function $\ell(x_0)$ should be smooth (more detailed conditions will be given shortly). Similarly as in the previous sections, we consider a generalized version of ADMM with two types of block update rules: the period-T essentially cyclic rule and the randomized rule. The detailed algorithm is given in the algorithm below.

Algorithm 4. The flexible ADMM for problem (3.2).

Let $\mathcal{C}^1 = \{0, \dots, K\}$, $t = 0, 1, \dots$.
At each iteration $t+1$, do:

If $t+1 \geq 2$, pick an index set $\mathcal{C}^{t+1} \subseteq \{0, \dots, K\}$.

For $k = 1, \dots, K$
If $k \in \mathcal{C}^{t+1}$, then agent k updates x_k by

(3.4)
$$x_k^{t+1} = \arg \min_{x_k \in X_k} g_k(x_k) - \langle y^t, A_k x_k \rangle + \frac{\rho}{2} \left\| x_0^t - \sum_{j<k} A_j x_j^{t+1} - \sum_{j>k} A_j x_j^t - A_k x_k \right\|^2$$

Else $x_k^{t+1} = x_k^t$.
If $0 \in \mathcal{C}^{t+1}$, update the variable x_0 by

(3.5)
$$x_0^{t+1} = \arg \min_x \ell(x_0) + \langle y^t, x_0 \rangle + \frac{\rho}{2} \left\| x_0 - \sum_{k=1}^K A_k x_k^{t+1} \right\|^2.$$

Update the dual variable:

(3.6)
$$y^{t+1} = y^t + \rho \left(x_0^{t+1} - \sum_{k=1}^K A_k x_k^{t+1} \right).$$

Else $x_0^{t+1} = x_0^t$, $y^{t+1} = y^t$.

The analysis of Algorithm 4 follows a similar argument as that of Algorithm 3. Therefore we will only provide an outline for it.

First, we make the following assumptions in this section.
Assumption C.
C1. There exists a positive constant $L > 0$ such that

$$\|\nabla \ell(x) - \nabla \ell(z)\| \leq L \|x - z\| \quad \forall \, x, z.$$

Moreover, X_k's are closed convex sets; each A_k is full column rank so that $\lambda_{\min}(A_k^T A_k) > 0$, where $\lambda_{\min}$ denotes the minimum eigenvalue of a matrix.

C2. The penalty parameter ρ is chosen large enough such that

    (1) each x_k subproblem (3.4) as well as the x_0 subproblem (3.5) is strongly convex, with modulus $\{\gamma_k(\rho)\}_{k=1}^K$ and $\gamma(\rho)$, respectively;

    (2) $\rho\gamma(\rho) > 2L^2$ and that $\rho \geq L$.

C3. $f(x_1, \ldots, x_K)$ is lower bounded over $\prod_{k=1}^K X_k$.

C4. g_k is either smooth nonconvex or convex (possibly nonsmooth). For the former case, there exists $L_k > 0$ such that $\|\nabla g_k(x_k) - \nabla g_k(z_k)\| \leq L_k\|x_k - z_k\|$ for all $x_k, z_k \in X_k$.

Note that compared with Assumptions A and B, in this case we no longer require that each g_k be smooth. Define an index set $\mathcal{K} \subseteq \{1, \ldots, K\}$ such that g_k is convex if $k \in \mathcal{K}$ and nonconvex smooth otherwise. Further, the requirement that A_k is full column rank is needed to make the x_k subproblem (3.4) strongly convex.

Our convergence analysis consists of a series of lemmas whose proofs, for the most part, are omitted since they are similar to that of Lemmas 2.1–2.3.

LEMMA 3.1. *Suppose Assumption* C *is satisfied. Then for Algorithm* 4 *with either the essentially cyclic rule or the randomized rule, the following is true:*

$$\nabla\ell(x_0^{t+1}) = -y^{t+1}, \; if \; 0 \in \mathcal{C}^{t+1}, \quad L^2\|x_0^{t+1} - x_0^t\|^2 \geq \|y^{t+1} - y^t\|^2,$$
$$L^2\|x_0^{t+1} - x_0^{t(k)}\|^2 \geq \|y^{t+1} - y^{t(k)}\|^2, \; L^2\|\hat{x}_0^{t+1} - x_0^t\|^2 \geq \|\hat{y}^{t+1} - y^t\|^2.$$

LEMMA 3.2. *Suppose Assumption* C *is satisfied. Then for Algorithm* 4 *with either the essentially cyclic rule or the randomized rule, the following is true:*

$$L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}) - L(\{x_k^t\}, x_0^t; y^t)$$
$$(3.7) \qquad \leq \sum_{k \neq 0, k \in \mathcal{C}^{t+1}} -\frac{\gamma_k(\rho)}{2}\|x_k^{t+1} - x_k^t\|^2 - \left(\frac{\gamma(\rho)}{2} - \frac{L^2}{\rho}\right)\|x_0^{t+1} - x_0^t\|^2.$$

LEMMA 3.3. *Assume the same setup as in Lemma* 3.2. *Then the following limit exists and is bounded from below:*

$$(3.8) \qquad\qquad \lim_{t \to \infty} L(\{x_k^{t+1}\}, x_0^{t+1}; y^{t+1}).$$

Proof. We have the following series of inequalities:

$$L(\{x_k^{r+1}\}, x_0^{r+1}; y^{r+1})$$
$$= \sum_{k=1}^K g_k(x_k^{t+1}) + \ell(x_0^{t+1}) + \left\langle x_0^{t+1} - \sum_{k=1}^K A_k x_k^{t+1}, y^{t+1} \right\rangle + \frac{\rho}{2}\left\|x_0^{t+1} - \sum_{k=1}^K A_k x_k^{t+1}\right\|^2$$
$$= \sum_{k=1}^K g_k(x_k^{t+1}) + \ell(x_0^{t+1}) + \left\langle \sum_{k=1}^K A_k x_k^{t+1} - x_0^{t+1}, \nabla\ell(x_0^{t+1}) \right\rangle$$
$$+ \frac{\rho}{2}\left\|x_0^{t+1} - \sum_{k=1}^K A_k x_k^{t+1}\right\|^2$$
$$\geq \sum_{k=1}^K g_k(x_k^{t+1}) + \ell\left(\sum_{k=1}^K A_k x_k^{t+1}\right) + \frac{\rho - L}{2}\left\|x_0^{t+1} - \sum_{k=1}^K A_k x_k^{t+1}\right\|^2.$$

The last inequality comes from the fact that

$$\ell\left(\sum_{k=1}^{K} A_k x_k^{t+1}\right) \leq \ell(x_0^{t+1}) + \left\langle \sum_{k=1}^{K} A_k x_k^{t+1} - x_0^{t+1}, \nabla\ell(x_0^{t+1}) \right\rangle$$
$$+ \frac{L}{2}\left\| x_0^{t+1} - \sum_{k=1}^{K} A_k x_k^{t+1} \right\|^2 .$$

Using assumptions C2–C3 leads to the desired result.　□

We note that the above result holds true deterministically even if the randomized scheme is used. The reason is that at each iteration regardless of whether $0 \in \mathcal{C}^{t+1}$, we have $y^{t+1} = -\nabla\ell(x^{t+1})$ because these two variables are always updated at the same iteration. The rest of the proof is not dependent on the algorithm.

We have the following main result for the nonconvex consensus problem.

THEOREM 3.4. *Suppose that Assumption* C *holds. Then the following is true for Algorithm* 4, *either deterministically for the essentially cyclic update rule or a.s. for the randomized update rule:*

1. *We have* $\lim_{t\to\infty} \|\sum_k A_k x_k^{t+1} - x_0^{t+1}\| = 0$, $k = 1, \ldots, K$.
2. *Let* $(\{x_k^*\}, x_0^*, y^*)$ *denote any limit point of the sequence* $\{\{x_k^{t+1}\}, x_0^{t+1}, y^{t+1}\}$ *generated by Algorithm* 4. *Then* $(\{x_k^*\}, x_0^*, y^*)$ *is a stationary solution of problem* (3.2) *in the sense that*

$$x_k^* \in \arg\min_{x_k \in X_k} g_k(x_k) + \langle y^*, -A_k x_k \rangle, \ k \in \mathcal{K},$$
$$\langle x_k - x_k^*, \nabla g_k(x_k^*) - A_k^T y^* \rangle \geq 0 \quad \forall \ x_k \in X_k, \ k \notin \mathcal{K},$$
$$\nabla\ell(x_0^*) + y^* = 0,$$
$$\sum_{k=1}^{K} A_k x_k^* = x_0^*.$$

3. *If* X_k *is a compact set for all* k, *then Algorithm* 4 *converges to the set of stationary solutions of problem* (3.2), *i.e.,*

$$(3.9) \qquad\qquad \lim_{t\to\infty} \operatorname{dist}\left((\{x_k^t\}, x_0^t, y^t); Z^*\right) = 0,$$

where Z^* *is the set of primal-dual stationary solutions for problem* (3.2).

The following corollary specializes the previous convergence result to the case where all g_k's as well as ℓ are convex (but not necessarily strongly convex). We emphasize that this is still a nontrivial result, since unlike [27, 29, 31, 34], we do not require the dual stepsize to be small or the g_k's and ℓ to be strongly convex. Therefore it is not known whether the classical ADMM converges for the multiblock problem (3.2), even for the convex case.

COROLLARY 3.5. *Suppose that Assumptions* C1 *and* C3 *hold and that* g_k *and* ℓ *are convex. Further, suppose that Assumption* C2 *is weakened with the following assumption:*

C2. *The penalty parameter* ρ *is chosen large enough such that* $\rho > \sqrt{2}L$.

Then the flexible ADMM algorithm (i.e., Algorithm 4*) converges to the set of primal-dual optimal solutions* $(\{x_k^*\}, x^*, y^*)$ *of problem* (2.2), *either deterministically for the essentially cyclic update rule or a.s. for the randomized update rule.*

Similar to the consensus problem, one can extend Algorithm 4 to its proximal version. Here the benefit offered by the proximal-type algorithms is twofold: *(i)* one

can remove the strong convexity requirement posed in Assumption C2(1); (ii) one can allow an inexact and simple update for each block variable. However, the analysis is a bit more involved, as the penalty parameter ρ as well as the proximal coefficient for each subproblem needs to be carefully bounded. Due to the fact that the analysis follows steps almost identical to those in section 2.3, we will not present them here.

4. Extensions. In this paper, we analyze the behavior of the ADMM method in the absence of convexity. We show that when the penalty parameter is chosen sufficiently large, the ADMM and several of its variants converge to the set of stationary solutions for certain consensus and sharing problems.

Our analysis is based on using the augmented Lagrangian as a potential function to guide the iterate convergence. This approach may be extended to other nonconvex problems. In particular, if the following set of sufficient conditions (see Assumption D below) are satisfied, then the convergence of the ADMM is guaranteed for the nonconvex problem (1.1). It is important to note that in practice these conditions should be verified case by case for different applications, just as we have done for the consensus and sharing problems.

Assumption D.
D1. The iterations are well defined, meaning the function $L(x^t; y^t)$ is uniformly lower bounded for all t.
D2. There exists a constant $\sigma > 0$ such that $\|y^{t+1} - y^t\|^2 \leq \sigma \|x^{t+1} - x^t\|^2$ for all t.
D3. $g_k(\cdot)$ is either smooth nonconvex or nonsmooth convex. The coupling function $\ell(\cdot)$ is smooth with Lipschitz continuous gradient L. Moreover, $\ell(\cdot)$ is convex with respect to each block variable x_k but is not necessarily jointly convex with x. X_k is a closed convex set. Problem (1.1) is feasible, that is, $\{x \mid Ax = q\} \bigcap_{k=1}^{K} \text{relint} X_k \neq \emptyset$.
D4. The penalty parameter ρ is chosen large enough such that each subproblem is strongly convex with modulus $\gamma_k(\rho)$, which is a nondecreasing function of ρ. Further, $\rho\gamma_k(\rho) > 2\sigma$ for all k.

Following a similar argument leading to Theorem 2.4, we can show that as long as Assumption D is satisfied, then the primal feasibility gap $\|q - \sum_{k=1}^{K} A_k x_k^{t+1}\|$ goes to zero in the limit and that every limit point of the sequence $\{\{x_k^{t+1}\}, x_0^{t+1}, y^{t+1}\}$ is a stationary solution of problem (1.1). A few remarks on Assumption D are in order:

1. Assumption D1 is necessary for showing convergence. Without D1, even if one is able to show that the augmented Lagrangian is decreasing, one cannot claim the convergence to stationary solutions. The reason is that the augmented Lagrangian may go to $-\infty$,[1] and therefore there is no way to guarantee that the successive difference of the iterates goes to 0, or the primal feasibility is satisfied in the limit.
2. The main drawback of Assumption D is that it is made on the iterates rather than on the problem. For different linearly constrained optimization problems, one still needs to verify that these conditions are indeed valid, as we have done for the consensus and the sharing problem considered in this paper.

---

[1] In fact, it is very easy to modify the algorithm so that the augmented Lagrangian reduces at each iteration—just change the "+" in the dual update (2.12) to "−." However, it is obvious that by doing this the dual variables will become unbounded, and the primal feasibility will never be satisfied.

Here we mention one more family of problems for which Assumption D can be verified. Consider

$$\min \quad f(x_1) + g(x_2)$$
(4.1)
$$\text{s.t.} \quad Bx_1 + Ax_2 = c, \; x_1 \in X,$$

where $f(\cdot)$ is a convex possibly nonsmooth function; $g(\cdot)$ is a possibly nonconvex function and has Lipschitzian gradient with modulus L_g; $X \subseteq R^N$; A is an invertible matrix; and $g(\cdot)$ and $f(\cdot)$ are lower bounded over the set X. Consider the following ADMM method, where the iterate generated at iteration $t + 1$ is given by

$$x_1^{t+1} = \arg \min_{x_1 \in X} \; f(x_1) + \langle Bx_1 + Ax_2^t - c, y^t \rangle + \frac{\rho}{2} \| Bx_1 + Ax_2^t - c \|^2,$$

$$x_2^{t+1} = \arg \min \; g(x_2) + \langle Bx_1^{t+1} + Ax_2 - c, y^t \rangle + \frac{\rho}{2} \| Bx_1^{t+1} + Ax_2 - c \|^2,$$

$$y^{t+1} = y^t + \rho \left(Bx_1^{t+1} + Ax_2^{t+1} - c \right).$$

By using steps in Lemmas 2.1–2.3, one can verify that if $\rho > L_g / \lambda_{\min}(AA^T)$, then Assumption D1 holds true. By having ρ large enough and by using the invertibility of A, we can make the x_2 subproblem strongly convex, and then Assumption D4 holds true. Other assumptions can be verified along similar lines. Note that in this case the convergence can be obtained with a slightly weaker condition in which the x_1 subproblem is convex but not necessarily strongly convex.
